

Early Journal Content on JSTOR, Free to Anyone in the World

This article is one of nearly 500,000 scholarly works digitized and made freely available to everyone in the world by JSTOR.

Known as the Early Journal Content, this set of works include research articles, news, letters, and other writings published in more than 200 of the oldest leading academic journals. The works date from the mid-seventeenth to the early twentieth centuries.

We encourage people to read and share the Early Journal Content openly and to tell others that this resource exists. People may post this content online or redistribute in any way for non-commercial purposes.

JSTOR is a digital library of academic journals, books, and primary source objects. JSTOR helps people discover, use, and build upon a wide range of content through a powerful research and teaching platform, and preserves this content for future generations. JSTOR is part of ITHAKA, a not-for-profit organization that also includes Ithaka S+R and Portico. For more information about JSTOR, please contact support@jstor.org.

Oxidase of *Medicago*.—EULER and BOLIN²⁹ claim to have succeeded in purifying and determining the chemical constitution of the oxidase (laccase) of *Medicago*. The purification was greatly furthered by the discovery that the substance was not sensitive to high temperatures. By boiling the extracted juice, the protein bodies were thrown down, and by treatment with animal charcoal, the dextrin-like substances withdrawn. They concluded that this pure laccase consists of mono-, di-, and tribasic aliphatic oxy-acids. The presence of the citrate, malate, and mesoxalate of this base was certainly established, and it is almost certain that the glycolate is a fourth salt.

They have already³⁰ shown that various salts of this type will produce oxidations qualitatively and quantitatively, similar to those produced by the laccase of *Medicago*. They now extend these tests to the new salts found, and to mixtures of the salts, and find marked agreement between the oxidations produced by them and those produced by laccase.—WILLIAM CROCKER.

Origin of the cell wall.—In an extended paper on vegetative cell division in the higher plants, POSTMA³¹ pays particular attention to the origin and development of the cell wall. Half of the paper consists of an excellent presentation and discussion of the literature, while the writer's own researches deal with the stomata of *Aneimia fraxinifolia*, root tips of *Allium Cepa*, and stem tips of *Psilotum triquetrum*. In case of the peculiar, isolated stomata of *Aneimia*, the cell wall is formed as in other vegetative cells, and consequently the problem in the three forms is much the same. While the writer finds that the cell wall arises in greater or less connection with the spindle, the material of the spindle is not believed to furnish all the material for the beginning of the wall. A mother *Hautschicht* splitting into two daughter *Hautschichts*, as sometimes described, could not be found. A single plate with rather small figures is hardly sufficient to illustrate so difficult and so important a problem.—CHARLES J. CHAMBERLAIN.

Seedlings of monocotyledons.—EVANS³² has undertaken a somewhat extensive study of monocotyledonous seedlings and also of the mature embryos. Not only has the structure at various stages been investigated, but also the effect of deep and shallow seed-sowing. The present paper is a record of some of the results, chiefly those in reference to the "plumular meristem"; and a final paper will review all the facts and suggest the conclusions. The facts are to be used, in part, in connection with the question as to the origin of the lateral position of
